

Algorithm :-

START.

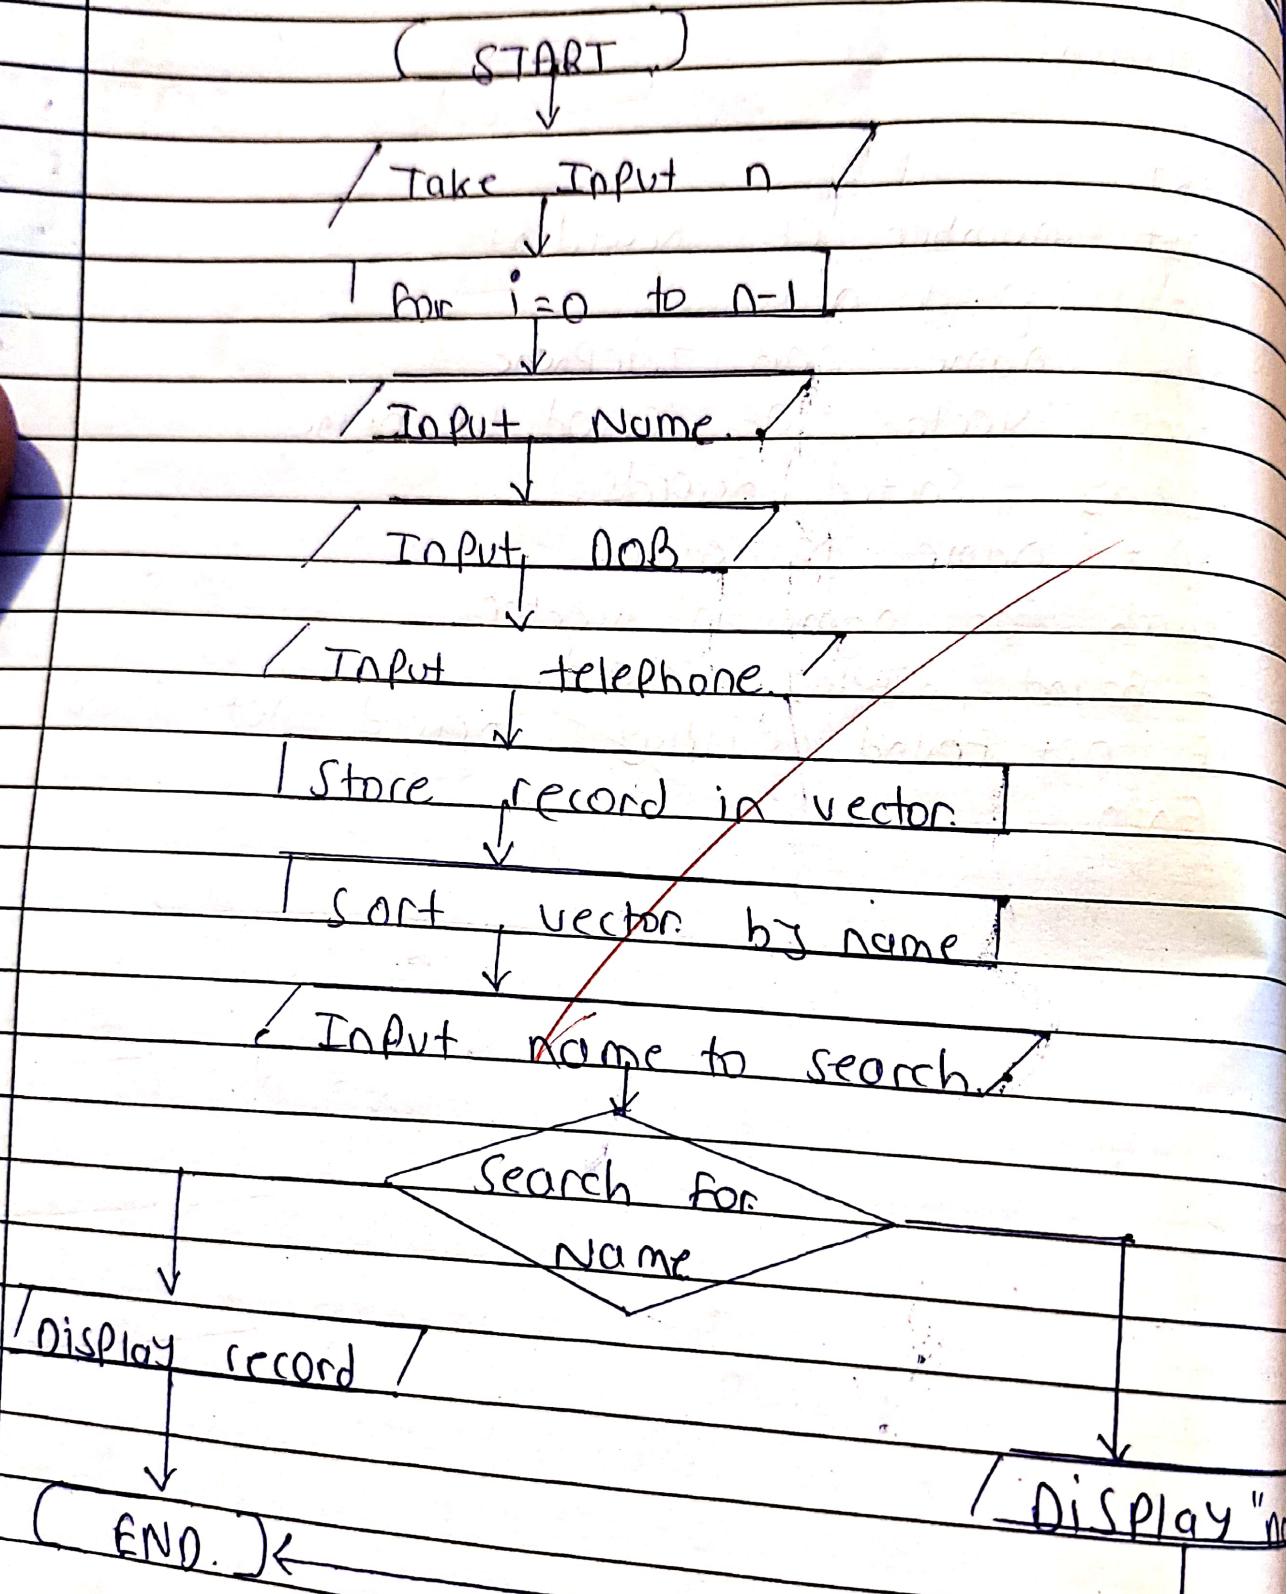

Initialize map : create map with state name & population

Input : user to enter a state name.

Search : look for state in map.

IF found display population.

END.

Algorithm:-

START.

Input number OF Record n)

for i = 0 to n-1

Input Name , DOB, Telephone

Stores vector OF record by name.

DISPLAY Sorted Records.

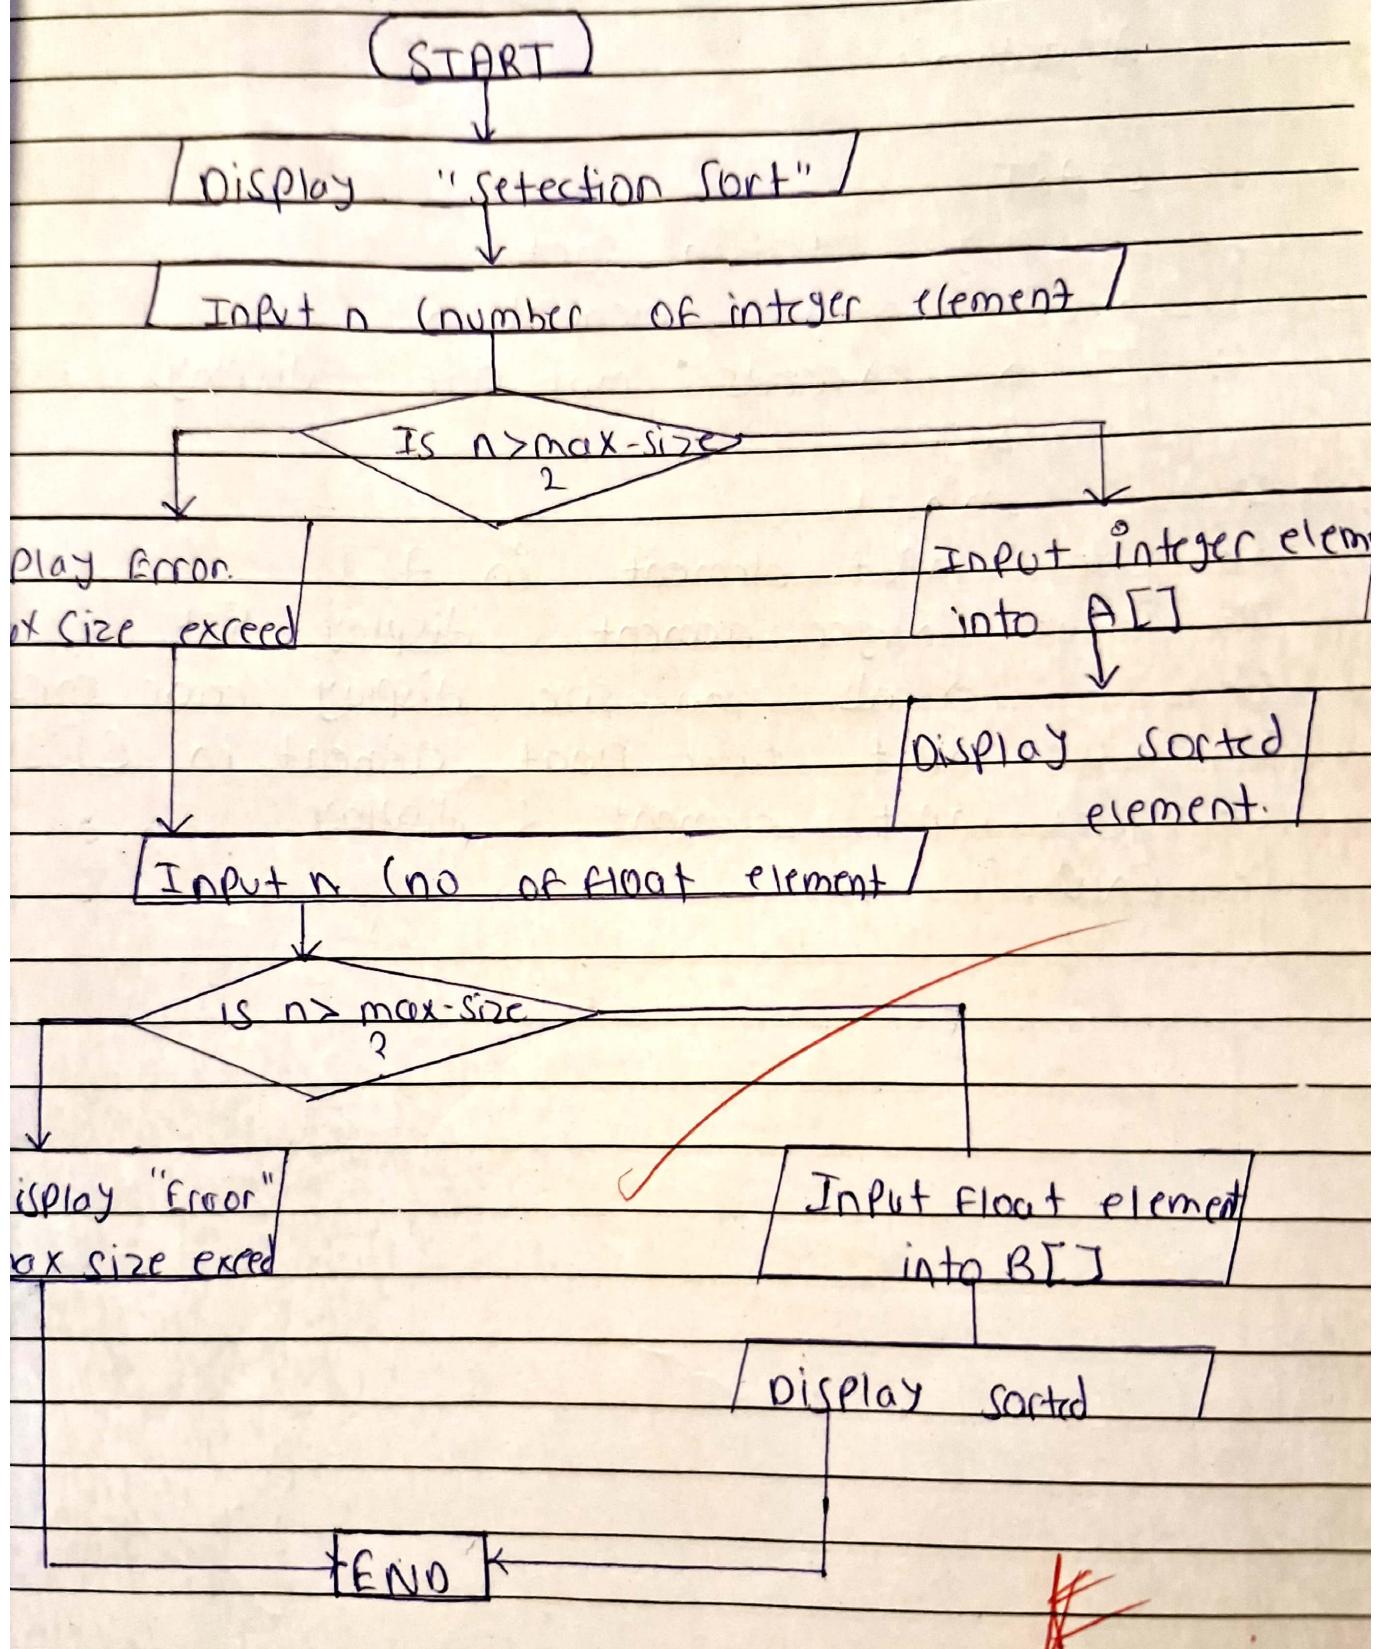

Input name to search.

Search for name in vector.

IF found, display record.

IF not found, display "Record Not Found"

END.

Algorithm:-

- 1) START
- 2) DISPLAY selection Sort
- 3) Read integer elements n.
- 4) IF n exceeds max size display error message.
- 5) Set min = 1
- 6) Sort input element in A[ ]
- 7) Input integer element & display list.
- 8) IF exceeds max-size display error message.
- 9) ELSE input take float element in B[ ]
- 10) Sort input element & display.
- 11) END.

START

declare employee class  
(name, emp-id, salary)

declare employee array o[5]  
fstream f variable i, n

Open file "input.txt"

Prompt user : "How many employees?"

Start loop  
(i=0 to n-1)

Accept employee detail using o[i]()

write employee detail to file f.write()

END loop

close file

read employee details from file f.read()

display employee details using o[i]

(END)

Conclusion:

START

include necessary header file (iostream & fstream)

define the employee class:

declare private data members:

- char name [20] for employee name.

- Two public member function accept() & display()  
In main function.

- create array o-s (employee o[s])

- declare stream object f.

open the file input.txt f.open ("input.txt")  
in write mode by calling

ask user for no of employee (n)

iterate over employee list.

use for loop (0 to n-1)

ask user to enter (name, emp-id, salary)

call accept () to take input.

close the file using (f.close())

reopen file inputc.txt in read mode by calling

f.open ("input.txt", ins :: in)

read & display employee info -

close file using (f.close())

END

START

declare classes: publication, book tape.

input choice : 1 for book , 2 for tape.

In choice 1 (book) or 2 (tape)

Case 1:

read data for  
book

Are Pages 500-1500  
& price 100-2000 ?

display  
details

Throw  
exception in  
b.get()

display  
detail

Throw  
excep  
get

1st time 30-90 m  
& price 500-1000

catch exc  
in main ()  
reset value.

Output error

H

Algorithm :

Step 1: Start

Step 2: Create  $P_1$  &  $P_2$  object of Person class

Step 3: Display header & details for  $P_1$  &  $P_2$ .

Step 4: Main menu operation.

- Input no of records n

- Create an array  $P_3$  of Person objects.

Step 5: Menu loop.

- display menu option.

- input user choice ch.

- if  $ch = 1$

- input name

- call  $P_3[x]$  get data (name)

Step 6: if  $ch == 2$

- display headers.

- for each record in  $B_3$ , call  $P_3[i]$

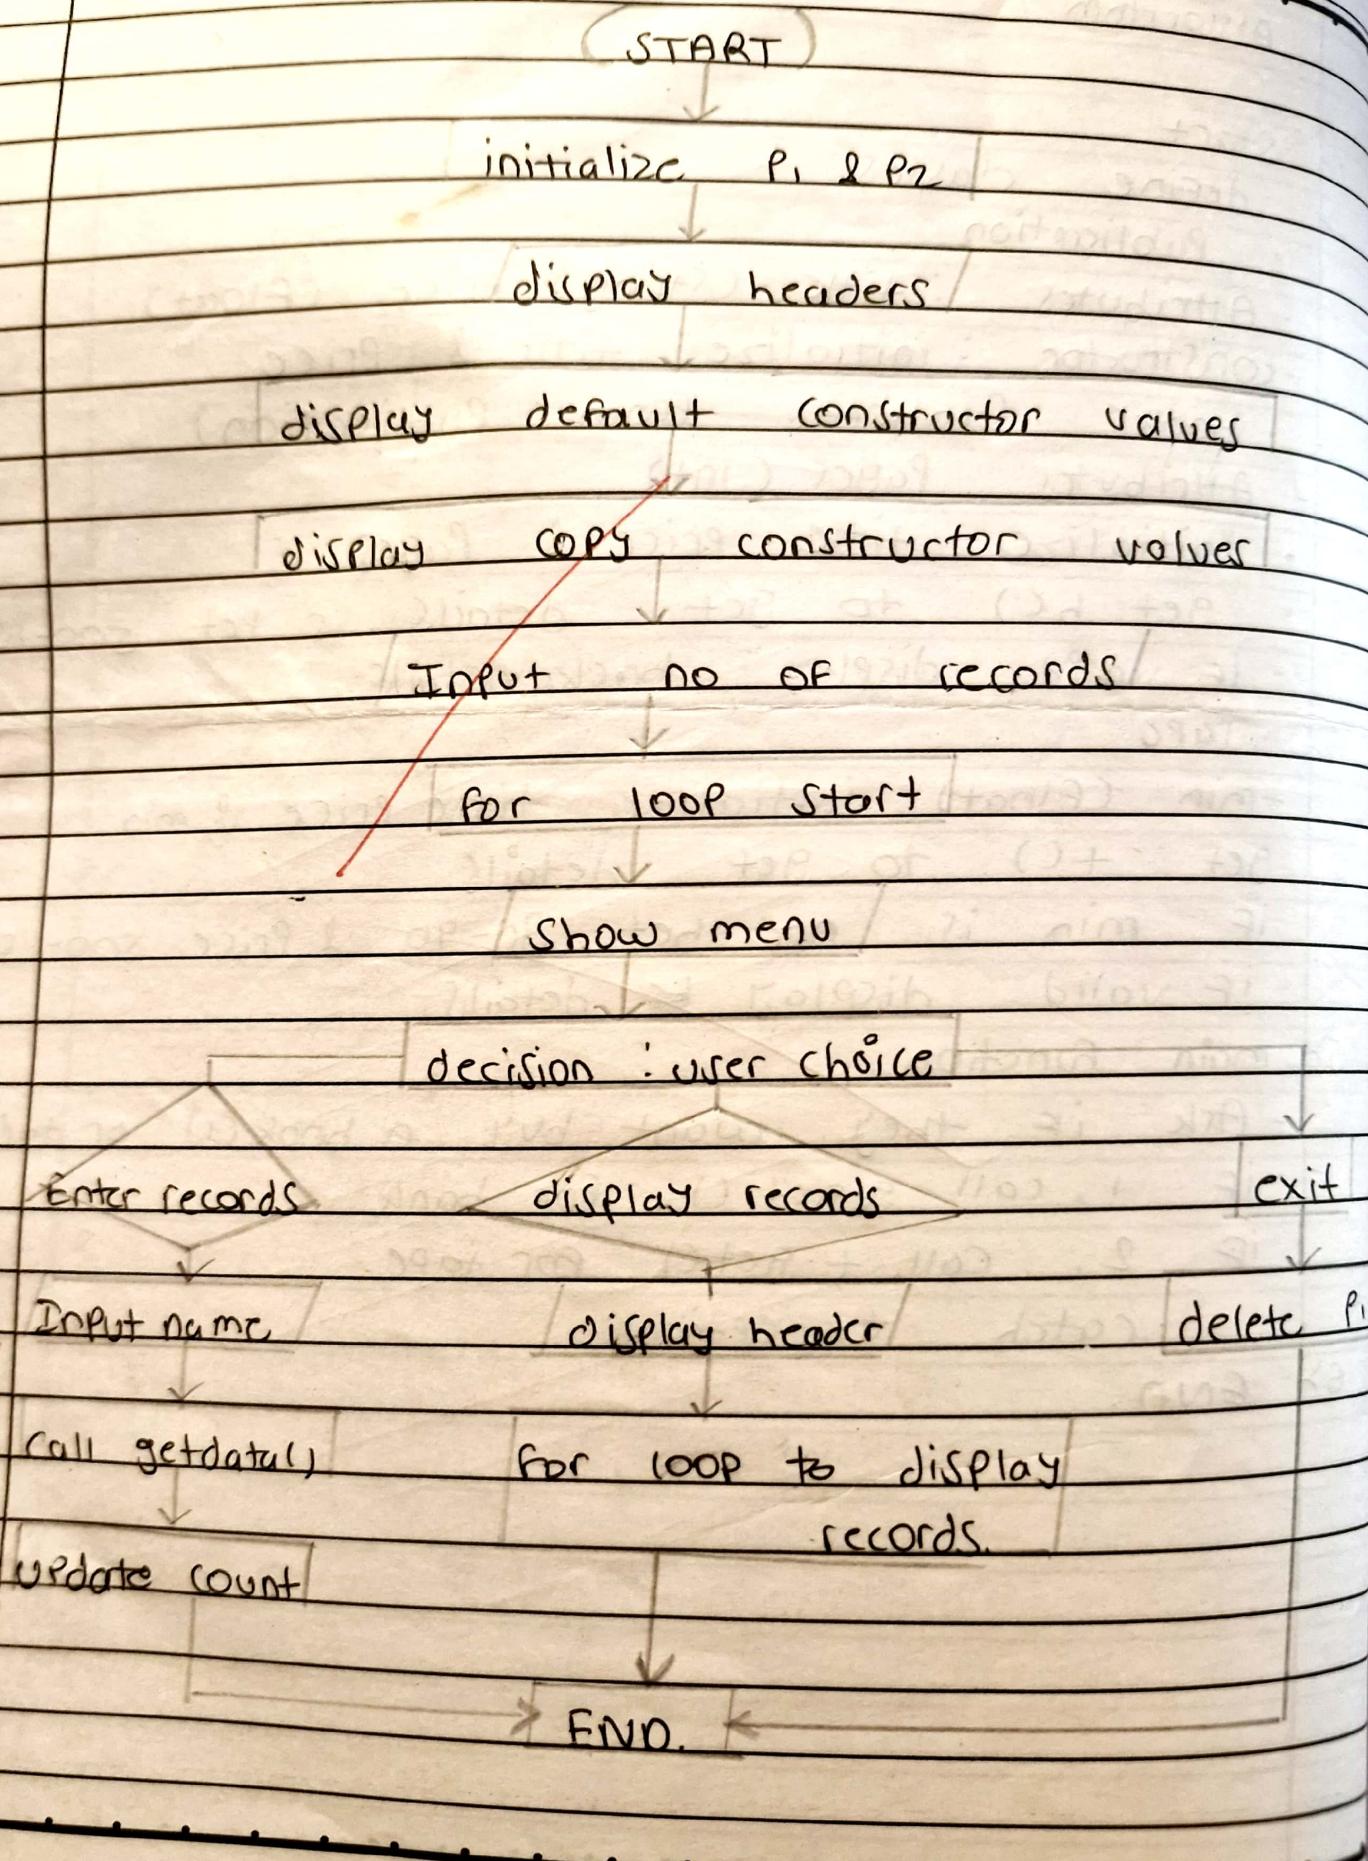

- if  $ch == 3$

- exit the loop.

Step 7: clean up

- delete  $P_1, P_2, P_3$ .

Step 8: END.

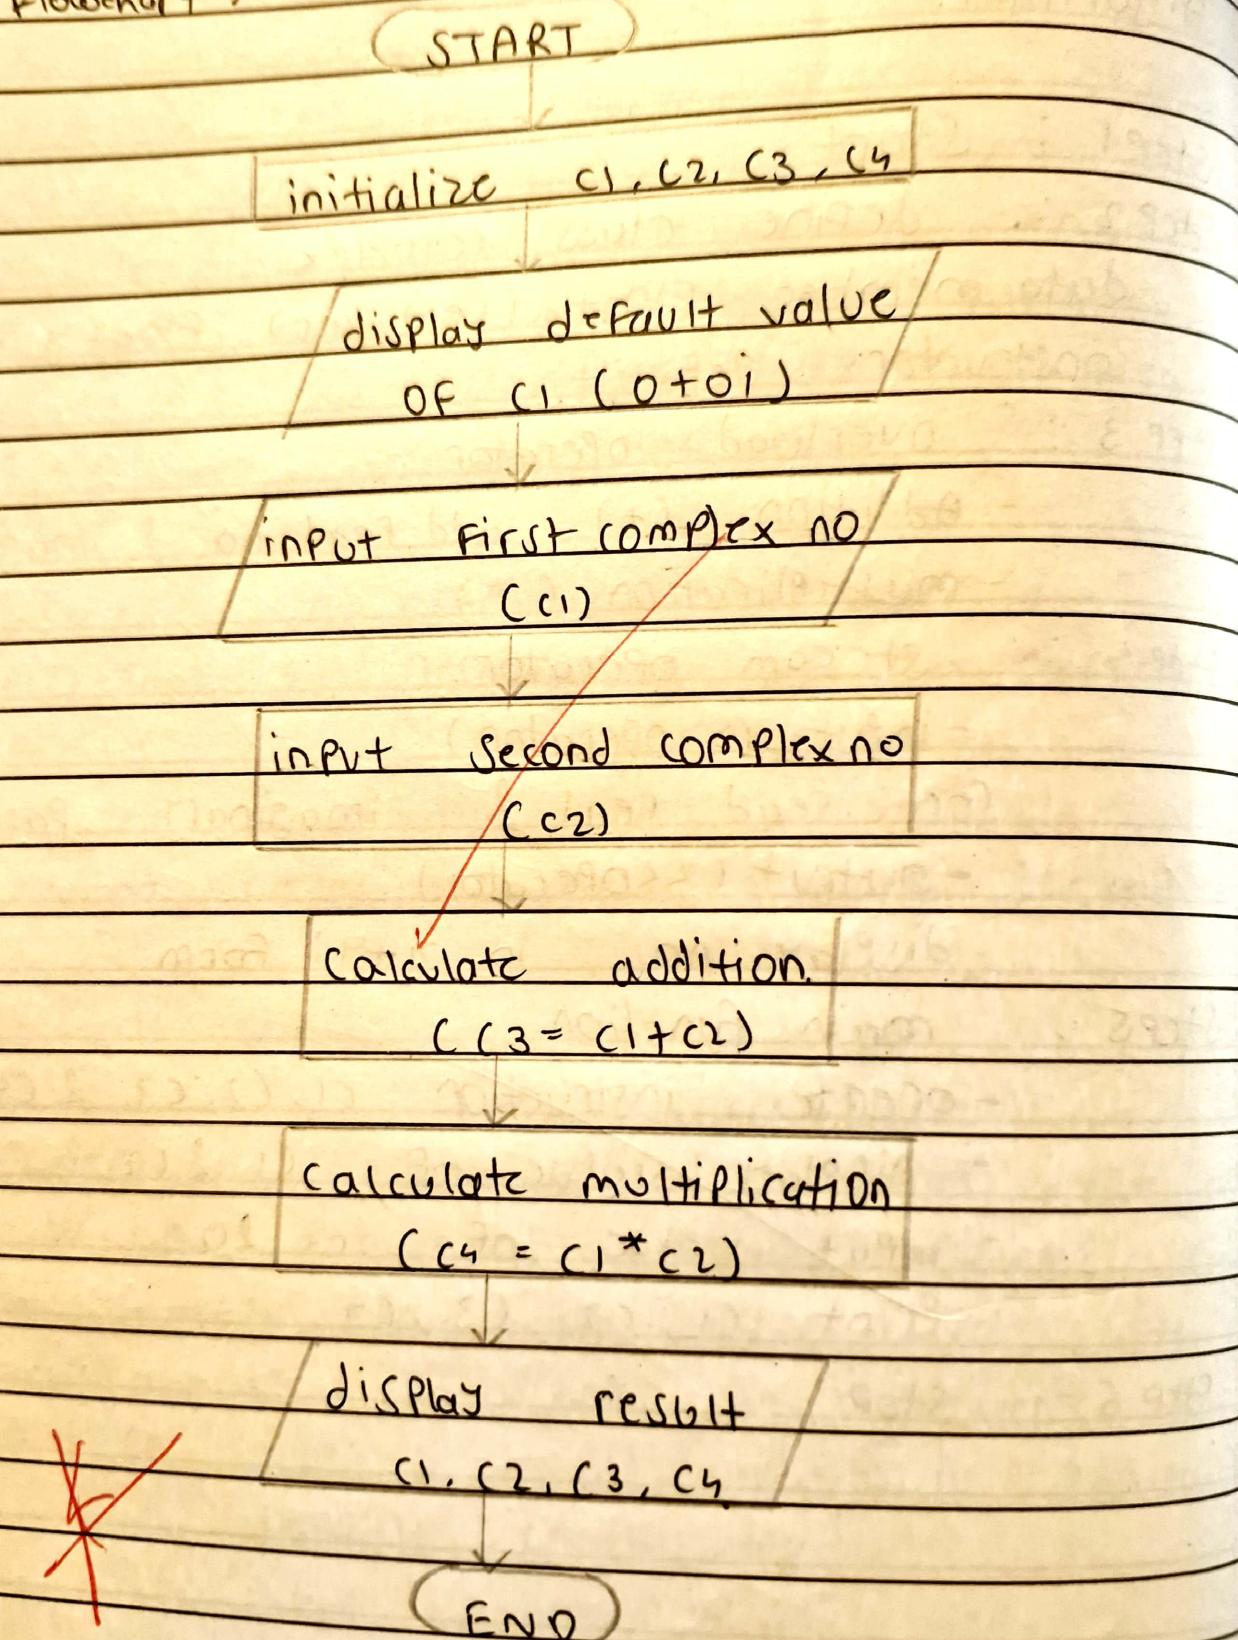

Algorithm :

- 1) Start
- 2) define classes
  - Publication
    - Attributes : title (String), price (float)
    - constructor : initialize title & price
- 3) • books (inherits from publication)
  - Attributes Pages (int)
  - initialize title, price & Pages
  - get b() to get details is bet 500-1500
  - if valid display book details.
- 4) • TAPC
  - min (float) initialize title price & min
  - get +() to get details
  - if min is not bet 30-90 & price 500-1000.
  - if valid display ~~be~~ details.
- 5) main function.
  - Ask if they want buy a book(1) or tape(2)
  - if 1, call g.get() for book.
  - if 2, call t.get() for tape.
  - catch exception.
- 6) END.

Flowchart :-

Algorithm:

Step 1 : Start

Step 2 : define class complex

- data member float  $x$  (real part), float  $y$ .

- constructor : default.

Step 3 : overload operator

- Addition (+) , add real no & imaginary.

- multiplication (\*)

Step 4 : stream operator.

- input (>>operator)

for read real & imaginary part.

- output (<<operator)

display no in  $n+yi$  form.

Step 5 : main function.

- create instruction  $c1, c2, c3, \& c4$ .

- display value of  $c1$  &  $c2$

- input value of  $c1$  to

- Print  $c1, c2, c3, c4$

Step 6 - stop.
